Lithium Destruction and Magnetic Confinement in the Solar Interior

Toby Wood

Department of Applied Mathematics and Statistics, UCSC

The Sun's internal structure

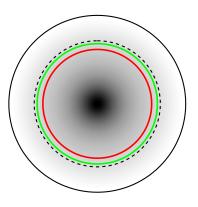

- Convection zone is well mixed by turbulence
- Radiation zone is stably stratified

Toby Wood (AMS)

The Sun's internal structure

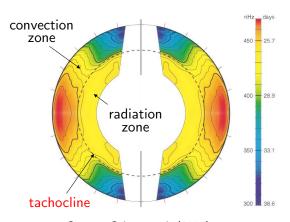

- $2.5 \times 10^6 \, \text{K}, \ 3 \times 10^6 \, \text{K}$
- Convection zone's lithium depleted by more than 99%
- Convection zone's beryllium not depleted

Toby Wood (AMS) The Solar Interior

The Sun's internal structure

Source: Schou et al. (1998)

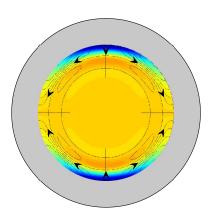

- Convection zone rotates differentially, poles 30% slower than equator
- Radiation zone rotates uniformly with a period of 27 days

Interior "mixing" by meridional circulation

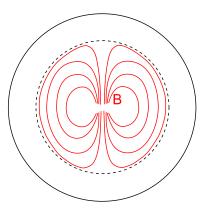

- Convection zone's differential rotation drives meridional flows that burrow into the interior (Spiegel & Zahn, 1992)
- The flows transport lithium, beryllium
 and angular momentum
- Polar regions spun down by angular momentum extraction

 Unchecked, the flows would by now have burrowed half-way to the center of the Sun

What stops the burrowing?

Uniform rotation can be explained by a suitably shaped, global-scale interior magnetic field ${\bf B}$ (e.g. Mestel & Weiss, 1987)

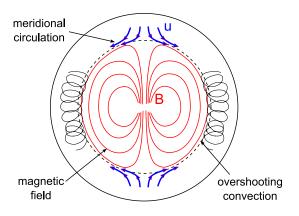

- Efficient angular momentum transport along field lines
- Ferraro's Law of Isorotation ($\mathbf{B} \cdot \nabla \Omega = 0$)

Magnetic confinement

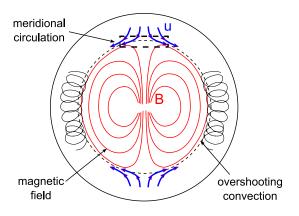

The magnetic field is confined in high latitudes by meridional flows (Gough & McIntyre, 1998)

... and in low latitudes by convective "magnetic flux pumping" (e.g. Tobias et al., 2001; Kitchatinov & Rüdiger, 2008)

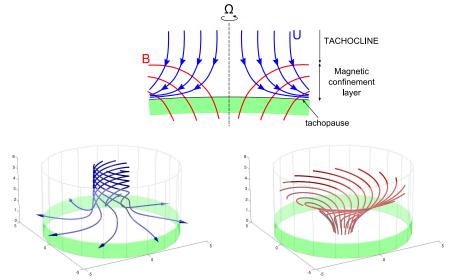

Magnetic confinement

The magnetic field is confined in high latitudes by meridional flows (Gough & McIntyre, 1998)

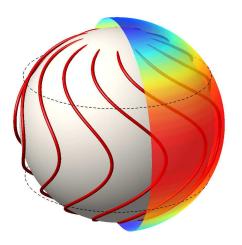

... and in low latitudes by convective "magnetic flux pumping" (e.g. Tobias et al., 2001; Kitchatinov & Rüdiger, 2008)

The high-latitude magnetic confinement layer

Wood & McIntyre (submitted)

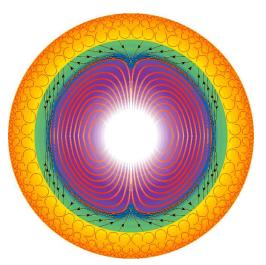

The global picture

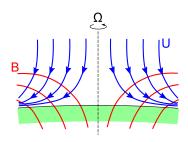

• Tachocline's latitudinal shear winds up the magnetic field lines, transmitting a prograde Alfvénic torque to high latitudes

How is lithium destroyed?

Gough & McIntyre (1998) suggested that meridional flows dig "polar pits" at the weak points of the magnetic field

How is lithium destroyed?

High-latitude confinement layer might form part of a broad polar pit
